

* Linear Regression:

* predict continuous numerical value by drawing straight line through data points using independent variable (x) and dependent variable (y).

eg:

Experience Vs. Salary

why bias is important?

→ eq: $y = 5400x$

and if $x = 0$ means year of experience is zero or he/she is fresher then their expected salary is,

$y = 5400 \times 0$

$= 0$ (which is false) either he has zero year of experience but salary cannot be zero.
